**Abstract:** The present research features such natural herbal extracts as rosemary (*Rosmarinus officinalis* L.), pomegranate (*Punica granatum* L.), and green tea (*Camellia sinensis* L.). Together with vitamin E, they were chosen to investigate hemp oil stability. The experiments revealed the effect of various fatty acids compositions on hemp oil properties. The effect of herbal extracts on the oxidative stability of oils was measured using the Rancimat method. The chemical tests included peroxide value (PV), free fatty acid (FFA) value, and acidity value (AV). Each herbal extract was applied in amounts of 30 mg/l and 50 mg/l. Vitamin E was mixed with the oil in the amount of 2 g/l. The changes in PV, FFA, AV, and fatty acid composition were measured on day 6, 12, 18, and 24. Hemp oil, pure or mixed with the extracts, was analyzed using the Rancimat method at 120°C with an airflow rate of 20 l/h to identify the induction periods (IP). IP values of oils with additional herbal extracts were found to be significantly higher (p < 0.05) than those of the control samples. The oil sample with vitamin E demonstrated the longest IP (4.12 hours at 120°C) during the Rancimat test. The herbal extracts and vitamin E had a positive effect on hemp oil PV compared with the control sample. Gas chromatography (GC) showed that hemp oil included a high amount of polyunsaturated Omega-3 fatty acids, and the oil was not resistant to oxidation. In general, the natural herbal extracts and vitamin E in the recommended quantities had a positive effect on the oxidative stability of hemp oil.

**Keywords:** Hemp oil, natural extracts, quality indicator, Rancimat, peroxide value

**INTRODUCTION**

Hemp (*Cannabis sativa* L.) is one of the oldest cultivated plants in history. Even though there seems to be no proved data about it, hemp was cultivated in Asia approximately 20,000 years ago [32]. As a rule, hemp is used as a fibre source. Most hemp seed sorts contain 20-35% of oil. Hemp oil is important for human diet due to its high polyunsaturated fatty acid content. Omega-6/Omega-3 ratio of hemp seed oil is similar with Mediterranean diets, which have great benefits for the cardiovascular system. According to the European Food Safety Agency, Omega-3 and Omega-6 ratio should be 1:3–1:5 [14]. Today, foods with a high amount of polyunsaturated fatty acids (PUFAs) are in greater demand than those with synthetic additives. However, there is a great competition to stabilize such products because they contain a lot of unsaturated fatty acids [22].

Hemp oil is extracted from hemp seeds by the cold pressed extraction method. As a rule, cold pressed oils are extracted from herbs or seeds by using a hydraulic press. The cold press method has several advantages compared with the more conventional solvent extraction method. First, it does not require heat processing or organic solvent. Second, the cold press method preserves such bioactive compounds as phenolics, essential fatty acids, tocopherols, and flavonoids, which improves the quality of oil [36].

Lipid oxidation often makes food unacceptable and decreases its nutritional quality due to the deterioration of essential fatty acids. Therefore, lipid oxidation is one of the important factors which define the quality and
shelf-life of vegetable oils and fats [12]. Under the oxidative degradation, fats and oils produce toxic compounds that are associated with various health issues [13]. Antioxidants are materials that prohibit oxidation of other compounds. Some natural antioxidants to be found in food include ascorbic acid, phenolic compounds, carotenoids, sterols, protein-based components, and sulphur-containing compounds [7]. Synthetic antioxidants are popular in food industry. However, the safety of synthetic materials remains a matter of discussion. It is now obligatory only natural antioxidants should be used in food industry to prevent the oxidative degradation of oils [6]. Herbs and spices contain a high amount of antioxidants due to phytochemicals [35].

In the last decade, many studies have showed that such herbs and spices as pomegranate, rosemary, various tea extracts, oregano, thyme, sage, etc. possess a high antioxidant capacity. It can be explained by the fact that they are rich in phenolic compounds [27]. For instance, pomegranate extract contains flavonoids, hydrolysable tannins, and anthocyanins [18]. Rosemary extract contains such phenolic diterpenes as carnosic acid, carnosol, and rosmanol, which are very effective antioxidants. Carnosic acid is one of the strongest antioxidant components to be found in rosemary extract [37]. Green tea extracts are rich in gallic acid derivatives and flavanols. In addition, green tea extracts contain a wide range of such flavour components as terpenes and organic acids. Green tea extracts are rich in catechins, epicatechin, epicatechin-3-gallate, epigallocatechin, and epigallocatechin-3-gallate [38].

The quality indicators of oils, such as oil stability index (OSI), fatty acid composition, PV, and AV, determine the quality of vegetable oils and fats. The Rancimat method evaluates antioxidants by measuring the changes in the conductivity induced by absorption of volatile organic acids. IP is the time needed for the secondary oxidation products to occur. IP defines the resistance properties of oils against oxidation. Thus, IP can be used to compare oil samples. On the other hand, fatty acid composition determines the stability of oils. Unsaturated fatty acids are especially prone to oxidation [15]. A higher rate of unsaturation makes the substance more oxygen-sensitive. Saturation of oils is measured with the help of GC, which also determines the fatty acids composition.

The determination of free fatty acid evaluates that the quantity of hydrolytic efficiency which occurs in the oil and as well as it shows intensity due to the reason of pro-oxidant effects of free fatty acids [16]. The determination of FFA evaluates that the quantity of hydrolytic efficiency which occurs in the oil and as well as it shows intensity due to the reason of pro-oxidant effects of free fatty acids [16]. The PV evaluates hydro peroxides composed throughout the early phase of rancidity of oils and fats. The process is usually settled on a titration with sodium thiosulphate. It evaluates the iodine released from potassium iodide according to peroxides in the oil [33]. In accordance with the Codex Alimentarius Commission [9], PV for cold pressed oils is < 15 meq/kg (milli-equivalents of peroxide per kg of oil). On the other hand, peroxide value demonstrates the current status of oxidation of oils and fats, and it does not indicate possible oxidation [27].

Hence, the purpose of the study was to investigate the quality parameters of hemp oil mixed with the different natural extracts and vitamin E. Indicators of oil hemp quality revealed some changes in fatty acids compositions and the quality properties. PV, OSI, AV, FFA, and fatty acid composition were evaluated on days 1, 6, 12, 18, and 24. Omega-3 and Omega-6 ratios were evaluated periodically under storage conditions. The research contributed to a better understanding of various vegetable oils and their oxidative and nutritional properties, as well as their feasibility for human diet.

**STUDY OBJECTS AND METHODS**

This research was carried out in the laboratory of Food Institute at Kaunas University of Technology. The fresh cold pressed hemp oil was purchased from JSC BORELA (Kaunas). The dried rosemary, green tea leaves, and dried pomegranate were purchased from a local Lithuanian company. Before extraction, the herbs were thoroughly crushed. All the extracts were prepared by pouring boiled deionized water over the dried herbs and stirring for 40 min. The temperature of the water was not maintained during the extraction. After that, the residue was prepared for the freeze drying process. The freeze drying process was applied in a Freeze Drying Plant Sublimator 15 (ZIRBUS Technology, Germany). The materials were placed on the shelf (300 × 400 mm) with the configuration of 5 shelves/80mm distance, 6/65, 7/55, 8/45. The parameters for the process were –45°C and –55°C; the condenser temperature was –18°C; the product temperature at the beginning of the process was –25°C; and the duration of the process was 12–20 hours. After lyophilization (freeze drying) process, the powdered samples were weighed and kept in a sterile plastic bag. Vitamin E was purchased from a local Lithuanian pharmacy. All other reagents for GC and chemical analysis were of analytical grade and obtained from Toronto Research Chemicals (Toronto, Canada). The samples were analyzed for different physicochemical parameters with the help of triple GC and the Rancimat test.

**Mixture preparation.** The hemp oil was mixed with the extracts of rosemary, green tea, pomegranate, and vitamin E. The extracts were applied in two different amounts: 30 mg/l and 50 mg/l. vitamin E was mixed with the oil at the amount of 2 g/l. During the experiment, all the samples were kept in the dark at room temperature.

**Rancimat analysis.** The accelerated Rancimat test was used to estimate the hemp oil stability to oxidation. The Rancimat apparatus was used with one evaluation mode. The induction period (IP) was defined as the time corresponding to the inflection point of the conductivity time curve. The Rancimat analysis was conducted using a Rancimat 892 (Metrohm, Herisau, Switzerland) according to the AOCS Official Method Cd 12b-92 [2]. Three grams of samples were put into the test tubes. Pure oil samples were considered as blank control samples. The oil samples were carefully poured into each reaction vessel not to push the substance into the oxy-
gen glass tube. The temperature of 120°C was set; the airflow rate was 20 l/h. IP was automatically determined from the inflection point of the curve by using the software supplied by the company.

**Peroxide value (PV) measurement.** PV indicates the state of primary oil oxidation. A high PV results from the history of oil, e.g., its exposure to such oxidation factors as high temperatures during processing and storage [19]. PV was determined according to ISO 3960* [20]. The oil samples (3 g each) were accurately weighed and mixed with isoctan/glacial acetic (3:2) solution. After that, potassium iodide mixture, water, and starch solution were applied. Finally, the mixtures were titrated with sodium thiosulfate, and the results were expressed in milliequivalents of active oxygen per kg of oil [23].

**Determination of free fatty acid (FFA) and acid value (AV).** FFA and AV of the oil samples were determined according to ISO 660:2009** without any modifications. FFA content is the number of milligrams of potassium hydroxide required to neutralize the FFA present in 1g of fat. The acidity content of FFAs was determined in accordance with the procedure specified in the International Standard (ISO 660:2009**). Approximately 5 g of oil samples were carefully weighed and mixed with ethanol (96%) and diethyl ether (peroxide free) in the ratio of 1:1. After that, phenolphthalein was added to the mixture. Finally, the mixtures were titrated with 0.1M sodium hydroxide. The results were expressed in oleic acid (282 g/mol) for the FFA and in milligrams per kg of oil [23].

**Fatty acid composition analysis.** The fatty acid composition analysis was based on the AOCS method [1]. The fatty acid composition was analyzed using an Agilent 7890 gas chromatograph coupled with an Agilent 5975 mass spectrometer (GC–MS; Agilent Technology, CA, USA). It was equipped with an HP-88 capillary column (100 mm × 0.25 mm id, 0.2 m film thickness). To prepare fatty acid methyl esters (FAME), oils were saponified with 0.5M KOH and then methylated by using 40% BF3 in methanol. The injection temperature was 250°C. Helium was used as a carrier gas at a pressure of 100 kPa. The split ratio was 1:30. The oven temperature was programmed according to the following sequence: 5 min at 80°C, then an increase up to 150°C at 10°C/min, 2 min at 150°C, followed by another increase up to 230°C at 5°C/min; and 10 min at 230°C. The ionization voltage was 70 eV; the scanning range was 50–550 m/z. Each fatty acid was quantified handling external norm. The fatty acids were expressed as g/100g.

**Statistical analysis.** All samplings and chemical analyses were tripled. The results of the study were expressed as a mean of the triplicate values with standard deviations.

**RESULTS AND DISCUSSION**

The experiment revealed that the small quantities of the extracts had no effect on such sensory properties of hemp oil as taste, color, and smell.

**Rancimat analysis.** Table 1 shows the effect of rosemary, pomegranate, green tea extracts, and vitamin E on the oxidative stability of the fresh hemp oil. The blank hemp oil oxidative stability IP value was 3.12 ± 0.02 h at 120°C; the airflow rate was 20 l/h. The control samples were the most visibly oxidized ones, which was demonstrated with the lowest IP values obtained. The IP values of oils with additional herbal extracts were found to be significantly larger (p < 0.05) than that in the control samples.

The Rancimat test assessed IP to detect the formal volatile acids throughout oil oxidation [25]. When vitamin E was added to the hemp oil, it resulted in the highest IP value (4.12 ± 0.04 h). This was because of the strong antioxidant capacity of the tocopherol content in vitamin E. When rosemary was added to the hemp oil, IP values were 3.69 ± 0.03 h (30 mg/l) and 3.89 ± 0.02 h (50 mg/l). IP values for the green tea were 3.67 ± 0.05 h (30 mg/l) and 3.3 ± 0.01 h (50 mg/l). IP values for the pomegranate extract were and 3.56 ± 0.06 h (30 mg/l) and 3.6 ± 0.03 h (50 mg/l). According to the results, the oils showed lower IP compared to the control sample. This means that the extracts had a high potential prevention of oxidative stability. According to Parker et al. [31], OSI was 8.5 hours for the cold pressed virgin (not refined) hemp seed oil (Wisconsin, USA) at 80°C and 7 l/h air flow rate.

![Fig. 1. PVs of hemp oil samples: 1 – control; 2 – green tea extract 30 mg/l; 3 – pomegranate extract 30 mg/l; 4 – pomegranate extract 50 mg/l; 5 – green tea extract 50 mg/l; 6 – rosemary extract 50 mg/l; 7 – vitamin E 2 g/l.](image-url)
The peroxide value characterizes the amount of hydro-peroxides created over the primary phase of oxidative rancidity of oils and fats [29]. A higher PV implicates a lower oxidative stability [28]. According to the Codex Alimentarius Commission (1999), PV of refined oils cannot exceed 10 meq/kg, PV of cold pressed virgin oils cannot exceed 15 meq/kg. According to Rossel [33], fresh refined oil must have a PV < 1 meq/kg. However, some oils acquired an off-flavour after refining PVs up to 10 meq/kg at storage condition. PV indicates good relation with flavor scores. However, PV is restricted to the primary stages of oxidation and gives an indication of the available status of oxidation. It does not demonstrate potential oxidation.

**Free fatty acids (FFA) and acidity value (AV).**

Fig. 2 shows FFA values of the hemp oil samples. By day 24, there was a slightly lower rise in FFA in the herbal and vitamin E samples. The FFA of the blank sample demonstrated a more significant increase, if compared to the other samples. The samples with the 2 g/l concentration of vitamin E had the minimum FFA content by the end of the storage period. FFA values of the sample with rosemary extract (30 mg/l, 50 mg/l) were 0.65 ± 0.02 (% oleic acid) and 0.64 ± 0.01 (% oleic acid), respectively. The FFA values of the sample with pomegranate extract (30 mg/l, 50 mg/l) were 0.74 ± 0.03 (% oleic acid) and 0.72 ± 0.02 (% oleic acid), respectively. The FFA values of the sample with green tea extract (30 mg/l, 50 mg/l) were 0.67 ± 0.01 (% oleic acid) and 0.69 ± 0.02 (% oleic acid), respectively. The FFA values of the sample with vitamin E was 0.61 ± 0.03 (% oleic acid) by the end of the storage period. The FFA value of the control sample was 0.82 ± 0.01 (% oleic acid). The results were not significantly different (p < 0.05) from the control sample by day 24.

Fig. 3 shows the AVs of the hemp oil samples. At the beginning, AVs of the samples were not significantly different (p < 0.05) from the control sample. By day 24, AV of the control sample was 1.64 ±
0.01 mg KOH/g oil. The vitamin E sample demonstrated the lowest AV (1.28 ± 0.04 mg KOH/g oil). Compared to the blank sample, AVs increased slightly during the storage. The rosemary sample AVs were 1.32 ± 0.05 (30 mg/l) and 1.3 ± 0.06 (50 mg/l) mg KOH/g oil. The green tea AVs were 1.33 ± 0.02 (30 mg/l) and 1.32 ± 0.01 (50 mg/l) mg KOH/g oil. The pomegranate AVs were 1.36 ± 0.03 (30 mg/l) and 1.34 ± 0.02 (50 mg/l) mg KOH/g oil by the end of the storage period.

FFA value indicates hydrolysis of fats, more specifically, the existence of FFAs. FFAs appear because of the hydrolysis of triglycerides and could be supported by humidity content [30]. The FFA content of the samples increased during the storage period. FFA of the control sample demonstrated a more significant increase if compared with the other samples.

**Fatty acid composition.** The changes in the fatty acid compositions reveal the oxidative constancy and nutritional properties of oils. Table 2 shows the fatty acid composition of the hemp oil samples on day 0 and day 24. All the samples were found to contain similar amounts of specific fatty acids, monounsaturated fatty acids (MUFA), polyunsaturated fatty acids (PUFA), and saturated fatty acids (SFA). Linoleic acid (C18:2) and α-Linolenic acid (C18:3) predominated. The primary SFA content in the control sample was 10.67%. The levels of the SFA, and MUFA increased in all the samples by day 27. Some changes were considerable, while others were insignificant.

PUFA decreased for all the samples from day 0 to day 24. Vitamin E and natural extracts protected the unity of unsaturated fatty acids, if compared to the blank sample. According to Gargouri et al., the unsaturated fatty acids of the oils easily oxidized [17]. An increase in the number of double bonds in unsaturated fatty acids reduced the oxidative constant [8]. The addition of rosemary, green tea, pomegranate, and vitamin E into oils can be an applicable and effective attempt to preserve the oil from oxidation during storage. Furthermore, natural extracts offer oil industry a novel opportunity to protect unsaturated fatty acids. Thus, vitamin E, rosemary, pomegranate, and green tea extracts provide extra conservation to vegetable oils and fats and improve their nutritional values.

**CONCLUSION**

While being one of the oldest cultivated plants in history, hemp (Cannabis sativa L.) still remains one of the most popular herbs in various branches of industry. Hemp seed oil possesses very important ingredients that have a beneficial effect on human health, e.g. various antioxidants, Omega-3 and Omega-6 fatty acids, etc. However, hemp oil is very unstable against oxidation due to its high content of PUFAs. Rosemary, green tea, pomegranate extracts, and vitamin E can have a positive effect on hemp oil quality. The Rancimat method and other chemical tests proved the positive effect of these extracts on the oxidative stability of hemp oil. The experiment measures the changes in PV, FFA, AV, and fatty acid composition. Thus, natural ingredients raise the quality of oils and can be recommended for oil manufacturers.
